

# Development of a Framework for Retrieval of Parameters of the Starlink Dish

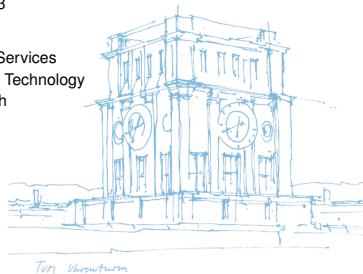

Final talk for the IDP by

**Roberto Castellotti**

advised by Leander Seidlitz, Johannes Zirngibl

Monday 27<sup>th</sup> November, 2023

Chair of Network Architectures and Services  
School of Computation, Information, and Technology  
Technical University of Munich

## What is Starlink?

- Starlink is a Low Earth Orbiting (LEO) Satellite Constellation
- Brings Internet connection to remote areas
- 4000+ satellites with plans to launch more
- End users have a Dish to connect to satellites in sight
- Performance is higher compared to geostationary satellites (GEOSAT) based connections
- Satellites are orbiting at 550 km in height vs GEOSAT's 35,000 km
- Average latency is 35 ms
- Download bandwidth is  $> 100$  MBps

## Starlink 101

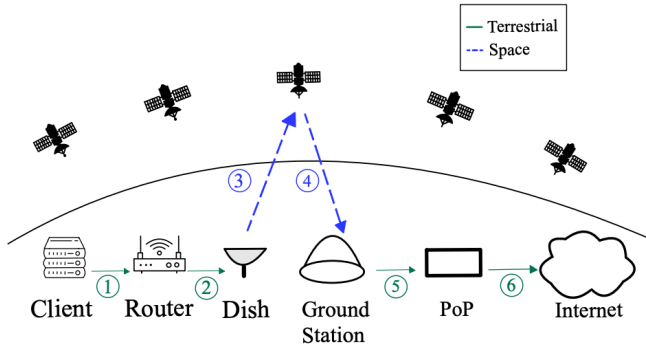

Figure 1: Starlink in a nutshell (ignoring Inter Satellite Links), from [1]

## Our Dish

Figure 2: Our Starlink Dish

## Problem Statement

should i remove this slide?

- Documenting gRPC API
- Measuring Latency to Point of Presence
- Understanding Routing Decisions
- Visualize Visible Satellites and patterns in their appearance
- Physical Layer Influences on Performance
- Retrieval of Obstruction Maps
- Satellite Handovers detection based on Obstruction Maps
- Correlation between Satellite Handovers and Bandwidth Drops

## Documenting the gRPC API

We started by documenting the gRPC API running on the Dish

- We started by documenting the gRPC<sup>1</sup> API running on the dish
- API is running at 192.168.100.1:9200
- The dish exposes a gRPC API with "Server Reflection"<sup>2</sup>
- 55 Endpoints are available
  - Majority of them don't work
  - 2 categories of errors: Unimplemented, PermissionDenied and a some other errors
- Most interesting working Endpoints<sup>3</sup>:
  - reboot
  - get\_status
  - get\_obstruction\_map

---

<sup>1</sup> <https://grpc.io> is a RPC framework from Google

<sup>2</sup> "Runtime construction of requests without having stub information precompiled into the client." <https://github.com/grpc/grpc/blob/master/doc/server-reflection.md>

<sup>3</sup> <https://gist.github.com/rcastellotti/e20630366dfeaeada6cc2680f562f6ac>

## Measuring Latency to the Point of Presence

- The `get_status` endpoint contains a `pop_ping_latency_ms` field
- We started polling the endpoint to gather latency to the Point of Presence
- Latency is pretty stable, averaging 35 ms with some irregular peaks

## Measuring Latency to the Point of Presence

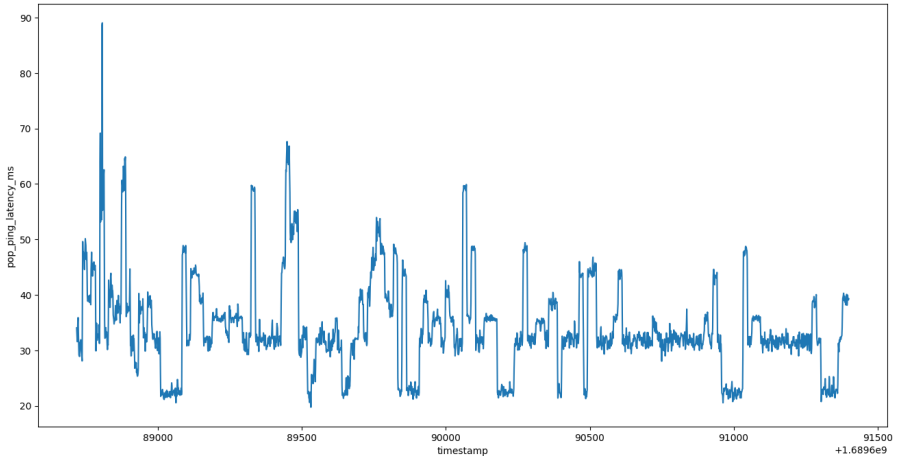

Figure 3: Visualizing latency to the Point of Presence.

## Understanding Routing Decisions

- Retrieved IP address blocks from major cloud providers (AWS,Azure,Oracle), position already known <sup>4</sup>
- Chose 5 geographically sparse targets around the globe, i.e for aws:
  - ap-northeast-2 Asia Pacific (Seoul)
  - us-east-1 US East (N. Virginia)
  - ap-south-1 Asia Pacific (Mumbai)
  - sa-east-1 South America (São Paulo)
  - me-south-1 Middle East (Bahrain)
- Tracerouted the targets over several days and saved data to later visualize it

---

<sup>4</sup> does not necessarily mean last hop will be in that area (little information around what happens inside datacenters), but a good enough approximation

## Understanding Routing Decisions

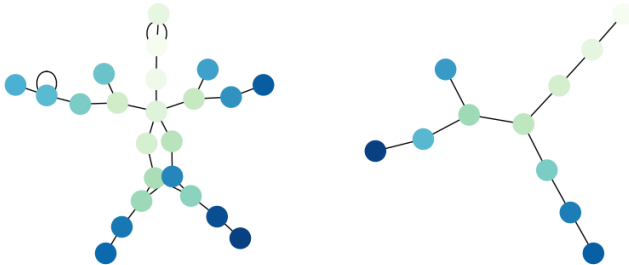

Figure 4: First 7 hops of traceroutes to 5 AWS datacenters using ICMP; left is Starlink, right is cabled connection

## Visualize Visible Satellites

- A two-line element set (TLE) is a data format encoding a list of orbital elements of an Earth-orbiting object for a given point in time, the epoch <sup>5</sup>
- Downloaded a list of Starlink's satellites TLEs from [celestrak.org](https://celestrak.org)
- Wrote a Python script to calculate visible satellites<sup>6</sup>
- Gathered information about satellites position and visualized patterns in Satellite appearances.

---

<sup>5</sup> [https://en.wikipedia.org/wiki/Two-line\\_element\\_set](https://en.wikipedia.org/wiki/Two-line_element_set)

<sup>6</sup> [https://gitlab.lrz.de/netintum/teaching/tumi8-theses/idp-castellotti/-/blob/main/common.py?ref\\_type=heads#L132](https://gitlab.lrz.de/netintum/teaching/tumi8-theses/idp-castellotti/-/blob/main/common.py?ref_type=heads#L132)

## Visualizing Patterns in Visible Satellites

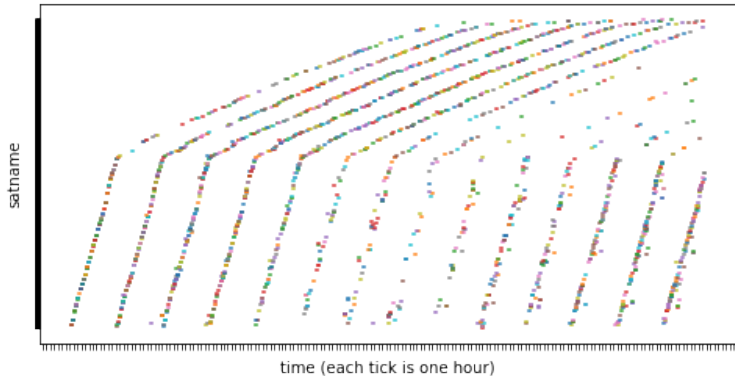

Figure 5: Visualizing patterns in Visible Satellites, we add a dot whenever we see a satellite

## Physical Layer Influences on Performance

Does the physical layer have any influences on performance?

- We wanted to understand whether the physical layer influences RTT
- The Dish may decide to send a packet only when it fills a buffer
- Sent packets to a host we control with iPerf to create traffic on the interface, varying the payload size
- Downloaded Debian ISOs from 5 different mirrors (to neutralize upload speed differences)
- Measured RTTs

## Physical Layer Influences on Performance

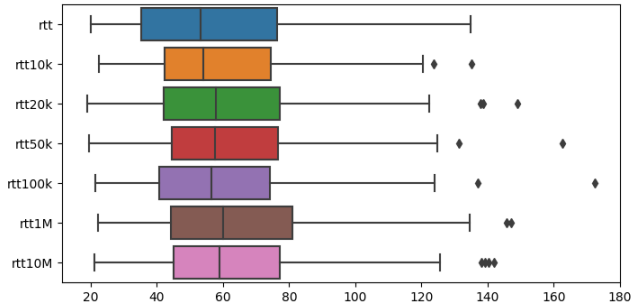

Figure 6: Physical Layer Influences on Performance

## the dish\_get\_obstruction\_map Endpoint

- An Obstruction Map captures the position where the dish has seen satellites
- Designed to provide a way to report whether the dish positioning is optimal
- Following the approach described by Izhikevich et al. [1] we retrieved maps
  - Reboot the Dish to clear the Obstruction Map (`api.reboot`)
  - Poll the endpoint frequently enough to see satellite traces (`api.get_obstruction_map`)
  - Save the maps to visualize them later

## Querying the dish\_get\_obstruction\_map Endpoint

```
"apiVersion":"9",  
"dishGetObstructionMap":{  
  "minElevationDeg":10.0,  
  "numCols":123,  
  "numRows":123,  
  "snr":[-1.0,-1.0,-1.0,-1.0,...,1.0,1.0,-1.0,-1.0]  
}
```

- Interpret the "snr" field as a matrix, it contains 15129 (123\*123) items
- Export this as images using Matplotlib, we add a timestamp for each map

Figure 7: An Obstruction Map

Figure 8: An Obstruction Map

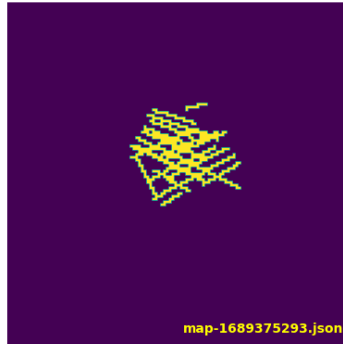

Figure 9: An Obstruction Map

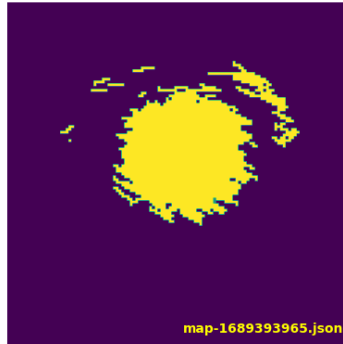

Figure 10: An Obstruction Map

## Detecting Handovers Algorithmically

- Going through visualizations frame by frame is not feasible (1000s of frames)
- Following the map matrix interpretation we assume:
  - "1" means a satellite was detected in that position
  - "-1" means no satellite was detected in that position
- Iterate through matrices two by two to and sum them
- Check if in the sum matrix "0" entry is "near" a "2" entry (inside a 3\*3 matrix)
  - If it is "near" **no handover was performed**
  - If it is in complete different position **an handover must have been performed**

## Obstruction Maps as Matrices (No Handover)

$$\begin{bmatrix} -1 & \color{red}{1} & -1 & -1 \\ -1 & -1 & \color{red}{1} & -1 \\ -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 \end{bmatrix} + \begin{bmatrix} -1 & \color{red}{1} & -1 & -1 \\ -1 & -1 & \color{red}{1} & -1 \\ -1 & -1 & -1 & \color{red}{1} \\ -1 & -1 & -1 & -1 \end{bmatrix} = \begin{bmatrix} -2 & 2 & -2 & -2 \\ -2 & -2 & 2 & -2 \\ -2 & -2 & -2 & \color{red}{0} \\ -2 & -2 & -2 & -2 \end{bmatrix}$$

## Obstruction Maps as Matrices (Handover)

$$\begin{bmatrix} -1 & -1 & \color{red}{1} & -1 \\ -1 & -1 & -1 & \color{red}{1} \\ -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 \end{bmatrix} + \begin{bmatrix} -1 & -1 & \color{red}{1} & -1 \\ -1 & -1 & -1 & \color{red}{1} \\ -1 & -1 & -1 & -1 \\ 1 & -1 & -1 & -1 \end{bmatrix} = \begin{bmatrix} -2 & -2 & 2 & -2 \\ -2 & -2 & -2 & 2 \\ -2 & -2 & -2 & -2 \\ \color{red}{0} & -2 & -2 & -2 \end{bmatrix}$$

## Correlating Satellite Handovers and Bandwidth Drops

- We now have an algorithm to detect handovers
- We run 2 scripts in parallel:
  - 1st: Retrieves an obstruction map every second
  - 2nd: Gathers Bandwidth data
- We visualize Bandwidth data and Satellite Handovers

## Correlating Satellite Handovers and Bandwidth Drops

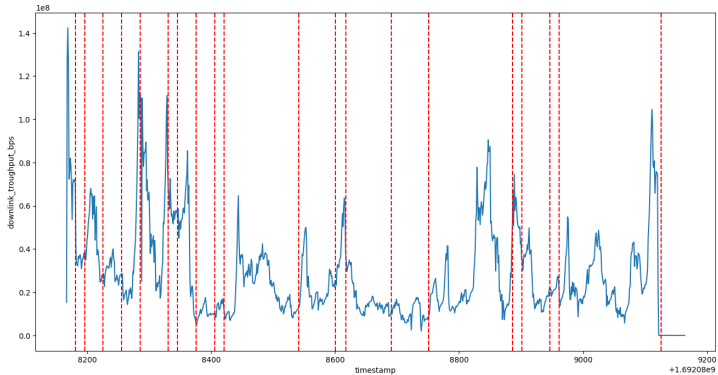

Figure 11: Correlating Satellite Handovers and Bandwidth Drops, blue is bandwidth, red vertical dashes are satellite handovers

## Similar Technologies

- Eutelsat operates a LEO constellation, Oneweb <sup>7</sup>, mainly serving Enterprises and Governments
- Amazon is currently launching its own LEO constellation: Project Kuiper <sup>8</sup>, with plans to launch 3,236 satellites, they secured launches (BlueOrigin)
- The China Aerospace Science and Technology Corporation plans to deploy a 13,000 satellite constellation <sup>9</sup>
- The increasing number of LEO satellites might pose some challenges, mainly:
  - Overall sky brightness increases (impacts astronomical observation)
  - Proliferation of debris

<sup>9</sup> <https://spacenews.com/china-to-begin-constructing-its-own-megaconstellation-later-this-year/>

## Final Remarks

We conclude that:

- Majority of the Endpoints on the gRPC API are not accessible
- PoP Latency is remarkably stable
- Physical layer has no remarkable influences on Performance
- Bandwidth is sustained consistently, even in the presence of satellite handovers
- Getting insights into inner routing is hard
